ITRP

Linear Collider Technology Recommendation

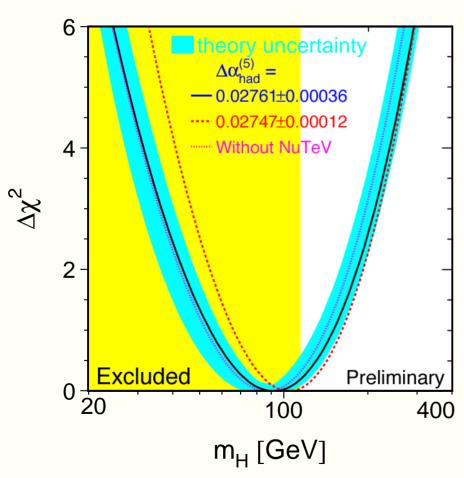

Barry Barish HEPAP Meeting Washington DC 23-Sept-04

Why ITRP?

- Two parallel developments over the past few years (the science & the technology)
 - The precision information from LEP and other data have pointed to a low mass Higgs; Understanding electroweak symmetry breaking, whether supersymmetry or an alternative, will require precision measurements.
 - There are strong arguments for the complementarity between a ~0.5-1.0 TeV LC and the LHC science.
 - Designs and technology demonstrations have matured on two technical approaches for an e⁺e⁻ collider that are well matched to our present understanding of the physics. (We note that a Cband option could have been adequate for a 500 GeV machine, if NLC/GLC and TESLA were not deemed mature designs).

Electroweak Precision Measurements

LEP results strongly point to a low mass Higgs and an energy scale for new physics < 1TeV

Why ITRP?

- Two parallel developments over the past few years (the science & the technology)
 - The precision information from LEP and other data have pointed to a low mass Higgs; Understanding electroweak symmetry breaking, whether supersymmetry or an alternative, will require precision measurements.
 - There are strong arguments for the complementarity between a ~0.5-1.0 TeV LC and the LHC science.
 - Designs and technology demonstrations have matured on two technical approaches for an e⁺e⁻ collider that are well matched to our present understanding of the physics. (We note that a Cband option could have been adequate for a 500 GeV machine, if NLC/GLC and TESLA were not deemed mature designs).

LHC/LC Complementarity

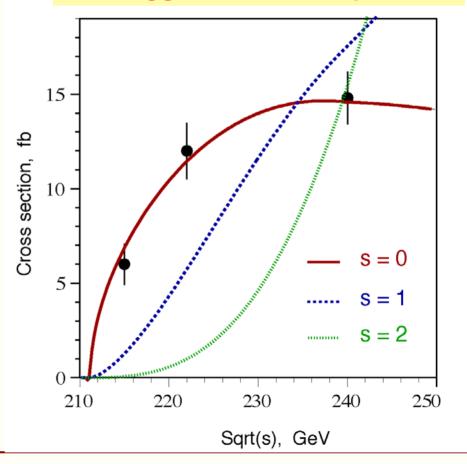

The 500 GeV Linear Collider Spin Measurement

LHC should discover the Higgs

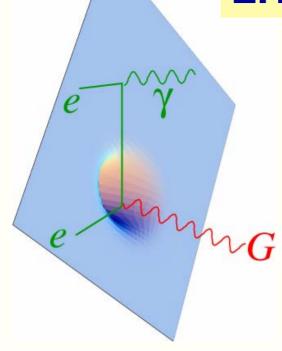

The linear collider will measure the spin of any Higgs it can produce.

The process $e^+e^- \rightarrow HZ$ can be used to measure the spin of a 120 GeV Higgs particle. The error bars are based on 20 fb⁻¹ of luminosity at each point.

The Higgs must have spin zero

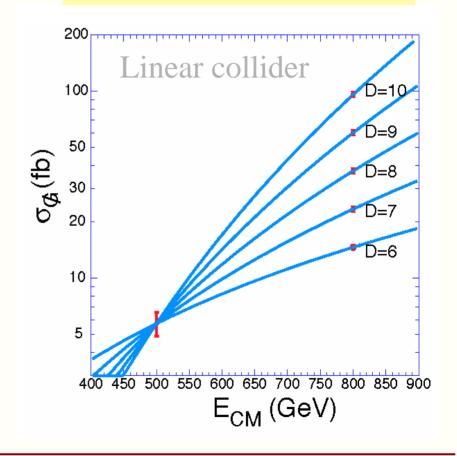

LHC/LC Complementarity

New space-time dimensions can be mapped by studying the emission of gravitons into the extra dimensions, together with a photon or jets emitted into the normal dimensions.

Extra Dimensions

Why ITRP?

- Two parallel developments over the past few years (the science & the technology)
 - The precision information from LEP and other data have pointed to a low mass Higgs; Understanding electroweak symmetry breaking, whether supersymmetry or an alternative, will require precision measurements.
 - There are strong arguments for the complementarity between a ~0.5-1.0 TeV I C and the LHC science.
 - Designs and technology demonstrations have matured on two technical approaches for an e⁺e⁻ collider that are well matched to our present understanding of the physics. (We note that a Cband option could have been adequate for a 500 GeV machine, if NLC/GLC and TESLA were not deemed mature designs).

CLIC

Why Decide Technology Now?

We have an embarrassment of riches !!!!

- Two alternate designs -- "warm" and "cold" have come to the stage where the show stoppers have been eliminated and the concepts are well understood.
- R & D is very expensive (especially D) and to move to the "next step" (being ready to construct such a machine within about 5 years) will require more money and a concentration of resources, organization and a worldwide effort.
- A major step toward a decision to construct a new machine will be enabled by uniting behind one technology, followed by a making a final global design based on the recommended technology.
- The final construction decision in ~5 years will be able to fully take into account early LHC and other physics developments.

ITRP Schedule of Events

Six Meetings

- RAL (Jan 27,28 2004)

Tutorial & Planning

- DESY (April 5,6 2004)
- SLAC (April 26,27 2004)
- KEK (May 25,26 2004)

Site Visits

- Caltech (June 28,29,30 2004) ____
 - **----**

Deliberations

Korea (August 11,12,13)

Recommendation

- ILCSC / ICFA (Aug 19)
- ILCSC (Sept 20)

Exec. Summary Final Report

International Technology Recommendation Panel Meeting August 11 ~ 13, 2004. Republic of Korea

Our Process

- We studied and evaluated a large amount of available materials
- We made site visits to DESY, KEK and SLAC to listen to presentations on the competing technologies and to see the test facilities first-hand.
- We have also heard presentations on both C-band and CLIC technologies
- We interacted with the community at LC workshops, individually and through various communications we received
- We developed a set of evaluation criteria (a matrix) and had each proponent answer a related set of questions to facilitate our evaluations.
- We assigned lots of internal homework to help guide our discussions and evaluations

What that Entailed

- We each traveled at least 75,000 miles
- We read approximately 3000 pages
- We had constant interactions with the community and with each other
- We gave up a good part of our "normal day jobs" for six months
- We had almost 100% attendance by all members at all meetings
- We worked incredibly hard to "turn over every rock" we could find.

from Norbert Holtkamp

The Charge to the International Technology Recommendation Panel

General Considerations

The International Technology Pecommendation Panel (the Panel) should recommend a Linear Collider (LC) technology to the International Linear Collider Steering Committee (ILCSC).

On the assumption that a linear collider construction commences before 2010 and given the assessment by the ITRC that both TESLA and ILC-Y/NLC have rather mature conceptual designs, the choice should be between these two designs. In necessary, a solution incorporating C-band technology should be evaluated.

Note -- We have interpreted our charge as being to recommend a technology, rather than choose a design

Evaluating the Criteria Matrix

- We analyzed the technology choice through studying a matrix having six general categories with specific items under each:
 - the scope and parameters specified by the ILCSC;
 - technical issues;
 - cost issues;
 - schedule issues;
 - physics operation issues;
 - and more general considerations that reflect the impact of the LC on science, technology and society
- We evaluated each of these categories with the help of answers to our "questions to the proponents," internal assignments and reviews, plus our own discussions

Evaluation: Scope and Parameters

- The Parameters Document describes a machine with physics operation between 200 and 500 GeV.
 - The luminosity of this machine must be sufficient to acquire 500 fb⁻¹ of luminosity in four years of running, after an initial year of commissioning.
 - The baseline machine must be such that its energy can be upgraded to approximately 1 TeV, as required by physics.
 - The upgraded machine should have luminosity sufficient to acquire 1 ab⁻¹ in an additional three or four years of running.
- The ITRP evaluated each technology in the light of these requirements, which reflect the science goals of the machine. It examined technical, cost, schedule and operational issues.

Evaluation: Scope and Parameters

- The Panel's general conclusion was that each technology would be capable, in time, of achieving the goals set forth in the Parameters Document.
- The Panel felt that the energy goals could be met by either technology.
 - The higher accelerating gradient of the warm technology would allow for a shorter main linac.
- The luminosity goals were deemed to be aggressive, with technical and schedule risk in each case.
 - On balance, the Panel judged the cold technology to be better able to provide stable beam conditions, and therefore more likely to achieve the necessary luminosity in a timely manner.

- The Panel was impressed with the state of CLIC R&D.
 - CLIC will face many challenges to demonstrate the feasibility of high-current beam-derived rf generation.
 - A vigorous effort to attack these issues at CTF3 at CERN.
- The Panel was also gratified to see the C-band progress
 - The C-band technology was originally conceived as an alternative to X-band for acceleration up to 500 GeV.
 - The technology is feasible and can be readily transferred to industry, with applications in science (XFELs) and industry (e.g. medical accelerators).
- The Panel evaluated the main linacs and subsystems for X-band and L-band to identify performance-limiting factors for construction and commissioning.

- In general, the Panel found the LC R&D to be far advanced. The global R&D effort uncovered a variety of issues that were mitigated through updated designs.
- For the warm technology, major subsystems were built to study actual performance.
 - The KEK damping ring was constructed to demonstrate the generation and damping of a high-intensity bunch train at the required emittance, together with its extraction with sufficient stability.
 - The Final Focus Test Beam at SLAC was constructed to demonstrate demagnification of a beam accelerated in the linac.
 - As a result, the subsystem designs are more advanced for the warm technology.

- In general, the cold technology carries higher risk in the accelerator subsystems other than the linacs, while the warm technology has higher risk in the main linacs and their individual components.
- The accelerating structures have risks that were deemed to be comparable in the two technologies.
 - The warm X-band structures require demonstration of their ability to run safely at high gradients for long periods of time.
 - The cold superconducting cryomodules need to show that they can manage field emission at high gradients.
- For the cold, industrialization of the main linac components and rf systems is now well advanced.

- Many cold technology components will be tested over the coming few years in a reasonably large-scale prototype through construction of the superconducting XFEL at DESY.
- A superconducting linac has high intrinsic efficiency for beam acceleration, which leads to lower power consumption.
- The lower accelerating gradient in the superconducting cavities implies that the length of the main linac in a cold machine is greater than it would be in a warm machine of the same energy.
 - Future R&D must stress ways to extend the energy reach to 1 TeV, and even somewhat beyond.

- In a superconducting rf structure, the rf pulse length, the length of the bunch train, and interbunch time interval are all large. This offers many advantages.
- The disadvantages are mainly related to the complex and very long damping rings, and the large heat load on the production target for a conventional positron source, which might require a novel source design.
 - Storage rings are among the best-understood accelerator subsystems today, and much of this knowledge can be transferred to the linear collider damping rings.
 - Beam dynamics issues such as instabilities, ion effects, and intrabeam scattering have been well studied in those machines.

- Achieving design luminosity will be a critical measure of the collider's success. A number of arguments indicate it will be easier with the cold technology.
 - The cold technology permits greater tolerance to beam misalignments and other wakefield-related effects.
 - Natural advantage in emittance preservation because the wakefields are orders of magnitude smaller
 - The long bunch spacing eliminates multi-bunch effects and eases the application of feedback systems.
 - This feedback will facilitate the alignment of the nanometer beams at the collision point.
- For these reasons, we deem the cold machine to be more robust, even considering the inaccessibility of accelerating components within the cryogenic system.

Evaluation: Cost Issues

- The Panel spent considerable effort gathering and analyzing all information that is available regarding the total costs and the relative costs of the two options.
- At the present conceptual and pre-industrialized stage of the linear collider project, uncertainties in estimating the total costs are necessarily large.
- Although it might be thought that relative costing could be done with more certainty, there are additional complications in determining even the relative costs of the warm and cold technologies because of differences in design choices and differences in costing methods used in different regions.

Evaluation: Cost Issues

- Some of the important contributors to the uncertainties are:
 - Design and implementation plans for important technological components of each machine are in a preliminary state.
 - Differences in design philosophy by the proponents lead to differences in construction cost, as well as final performance.
 These cannot be resolved until a global and integrated design exists.
 - Assumptions about industrialization/learning curves for some key components have large uncertainties at this early stage in the design.
 - Present cost estimates have some regional philosophies or prejudices regarding how the project will be industrialized.
 Contingency accounting, management overheads, staff costs for construction and R&D costs for components are all treated differently; this adds uncertainty to cost comparisons.

Evaluation: Cost Issues

- Some of the important contributors to the uncertainties are: (continued)
 - In an international project, the procurement of substantial parts of the collider will be from outside the regions that prepared the present estimates, and this can considerably alter the costs.
 - The costs of operating the accelerator are also difficult to determine at this stage without a better definition of the reliability, access and staffing requirements, as well as the cost of power and component replacement.
- As a result of these considerations, the Panel concluded that comparable warm and cold machines, in terms of energy and luminosity, have total construction and lifetime operations costs that are within the present margin of errors of each other.

Evaluation: Schedule Issues

- In accordance with our charge, we assumed that LC construction would start before 2010, and that it would be preceded by a coordinated, globally collaborative effort of research, development, and engineering design.
- Based on our assessment of the technical readiness of both designs, we concluded that the technology choice will not significantly affect the likelihood of meeting the construction start milestone.
- We believe that the issues that will drive the schedule are primarily of a non-technical nature.

Evaluation: Physics Operations Issues

Several factors favor the cold machine:

- The long separation between bunches in a cold machine allows full integration of detector signals after each bunch crossing. In a warm machine, the pileup of energy from multiple bunch crossings is a potential problem, particularly in forward directions.
- The energy spread is somewhat smaller for the cold machine, which leads to better precision for measuring particle masses.
- If desired, in a cold machine the beams can be collided head-on in one of the interaction regions. Zero crossing angle might simplify shielding from background.
- a nonzero crossing angle permits the measurement of beam properties before and after the collision, giving added constraints on the determination of energy and polarization at the crossing point.

Evaluation: General Considerations

Linear collider R&D affects other scientific areas

- the development of high-gradient superconducting cavities is a breakthrough that will find applications in light sources and Xray free electron lasers, as well as in accelerators for intense neutrino sources, nuclear physics, and materials science.
- New light sources and XFELs will open new opportunities in biology and material sciences.
- The superconducting XFEL to be constructed at DESY is a direct spin-off from linear collider R&D.
- the R&D work done for the X-band rf technology is of great interest for accelerators used as radiation sources in medical applications, as well as for radar sources used in aircraft, ships and satellites, and other applications.

The Recommendation

- We recommend that the linear collider be based on superconducting rf technology
 - This recommendation is made with the understanding that we are recommending a technology, not a design. We expect the final design to be developed by a team drawn from the combined warm and cold linear collider communities, taking full advantage of the experience and expertise of both (from the Executive Summary).
 - The superconducting technology has several very nice features for application to a linear collider. They follow in part from the low rf frequency.

Some of the Features of SC Technology

- The large cavity aperture and long bunch interval reduce the complexity of operations, reduce the sensitivity to ground motion, permit inter-bunch feedback and may enable increased beam current.
- The main linac rf systems, the single largest technical cost elements, are of comparatively lower risk.
- The construction of the superconducting XFEL free electron laser will provide prototypes and test many aspects of the linac.
- The industrialization of most major components of the linac is underway.
- The use of superconducting cavities significantly reduces power consumption.

The ITRP Recommendation

- The ITRP recommendation was presented to ILCSC
 & ICFA on August 19 in a joint meeting in Beijing.
- ICFA unanimously endorsed the ITRP's recommendation on August 20 and J. Dorfan announced the result at the IHEP Conference
- The ITRP recommendation was discussed and endorsed at FALC (Funding Agencies for the Linear Collider) on September 17 at CERN.
- The final report of ITRP was submitted to ILCSC on September 20 and is now available.

What's Next?

- A new global design based on superconducting rf technology will be initiated by the combined warm and cold experts.
- We need to fully capitalize on the experience from SLC, FFTB, ATF and TTF as we move forward. The range of systems from sources to beam delivery in a LC is so broad that an optimized design can only emerge by pooling the expertise of all participants.
- The R&D leading to a final design for the ILC will be coordinated by an International Central Design Team, which the ITRP endorses.
- The first collaboration meeting will be at KEK in November.
